Thương Hồ Protocol:

Solving $O(1)$ State Bloat with Vietnamese Maritime Wisdom

Man on the boat in a river – Trang Trinh

🌊 The Inspiration: Stealth and Resilience

Decades ago, during the struggle for sovereignty, the "Unnumbered Ships" (Tàu Không Số) of Vietnam navigated through vast oceans, evading advanced radar detection by being small, agile, and decentralized. They delivered vital resources through a network of "Floating Markets" (Thương Hồ), where trust was built on contribution, not central authority.

Today, the digital world faces a similar challenge: **State Bloat**. Blockchain networks are becoming heavy, centralized, and vulnerable to the looming "Quantum Apocalypse."

Introducing **Thương Hồ Protocol (THP)**—a post-quantum, stateless infrastructure designed to bring "The Wisdom of the River" to the future of Web 4.0.

"For this Earth Day Challenge, we want to address the 'Silent Polluter': The massive energy consumption of Blockchain State Bloat. While traditional networks require giant, energy-hungry data centers to store terabytes of history, Thương Hồ Protocol utilizes $O(1)$ Verkle Trees. We compress proofs to ~2KB, allowing low-power smartphones to validate the network. **THP is inherently Green Tech**—designed not just to secure data, but to drastically reduce the carbon footprint of digital infrastructure, perfectly aligning with global ESG and climate adaptation goals."

🛠 The Problem: The Gravity of Data

Traditional blockchains require every node to store the entire history of the ledger. This leads to:

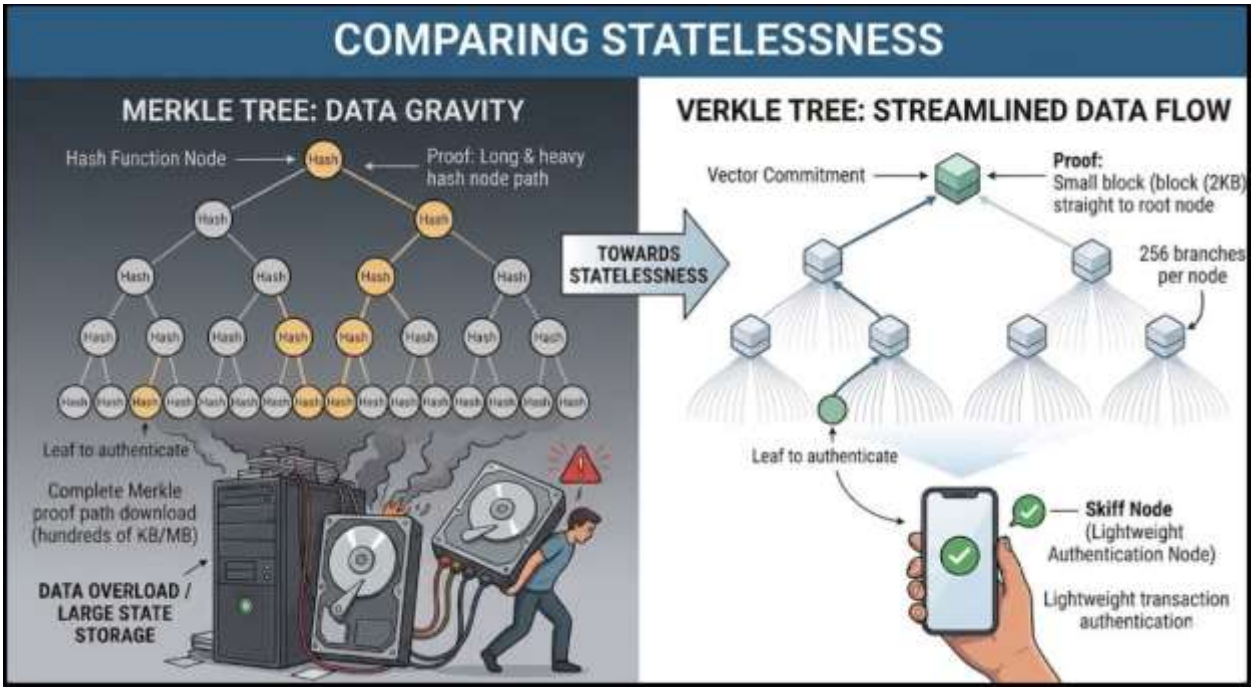
1. **State Bloat:** Full nodes become too expensive for average users.
2. **Centralization:** Only giant data centers can afford to validate the network.
3. **Quantum Vulnerability:** Existing ECDSA/RSA signatures will be broken by Shor's algorithm within the decade.

🚀 The Solution: Three Technical Pillars

1. Statelessness via $O(1)$ Verkle Trees

Instead of Merkle Trees, THP utilizes **256-ary Verkle Trees**. By using polynomial vector commitments, we compress verification proofs to a constant size (~2KB).

- **Result:** Even a decade from now, a simple smartphone (a "Skiff Node") can validate the entire state without downloading terabytes of data. **Efficiency is our tide.**



With the $O(1)$ Verkle Tree structure, we compress billions of transactions into a single 2KB proof. Efficiency is our tide.

Comparison Table: Merkle Tree vs. Verkle Tree
This table highlights why the Verkle Tree structure is the "key" to solving the State Bloat problem.

Feature	Merkle Tree (Traditional)	Verkle Tree (Thuong Ho Protocol)
Tree structure	Typically a binary tree.	Multi-branch tree (256-ary Verkle Trees).
Proof size	Increases logarithmically ($O(\log n)$), the more data there is, the larger the proof.	Constant size ($O(1)$), approximately ~2KB regardless of the data volume.
Verification mechanism	Based on layer-by-layer hashing.	Uses Polynomial Vector Commitments.
Hardware requirements	Requires a Full Node with massive storage to store the entire history.	Allows smartphones (Skiff Nodes) to verify without downloading terabytes of data.
Statelessness	Difficult to achieve due to overly bulky proofs.	Achieves perfect statelessness thanks to ultra-lightweight proofs.

2. Post-Quantum Resilience (Lattice-Based)

We don't just build for today; we build for the next century. THP anchors its security in the **Learning With Errors (LWE)** problem.

- Our signatures follow **NIST FIPS 203/204** standards, making the protocol immune to quantum-capable adversaries. **Security is our bedrock.**

3. ZK-Friendly Performance (Poseidon Hash)

To ensure privacy and speed on mobile devices, we replaced traditional hashes with the **Poseidon Hash function**.

- It reduces ZK-circuit constraints by **100x**, allowing farmers in the Mekong Delta to prove their ESG contributions or ODA receipts in under 2 seconds. **Speed is our current.**

Cruise through Mekong River Delta - Tomáš Malík

The 5R Digital Waste Framework: Aligning with Institutional ESG Standards

While our mathematical baseline proves a massive reduction in the CO2 footprint through stateless architecture, real-world Environmental, Social, and Governance (ESG) compliance requires a systemic approach. Drawing direct inspiration from the digital sustainability frameworks and tech pilots explored by the **World Bank's Innovation Lab** [1], Thương Hồ Protocol adapts the corporate "5R Framework" for physical waste into a rigorous methodology for **Digital Waste Management**:

- **Refuse:** Rejecting non-essential, heavy data storage at the consensus layer. We refuse to accept "State Bloat" as an inevitable byproduct of decentralized trust.
- **Reduce:** Compressing validation proofs to a constant ~2KB via $O(1)$ Verkle Trees, drastically reducing the CPU cycles and energy required for data transmission.
- **Reuse:** Utilizing standardized, modular smart contract architectures (like our MekongClimateFund PoC) to prevent redundant, energy-consuming on-chain deployments.

- **Repurpose:** Enabling lightweight "Skiff Nodes" (e.g., basic smartphones) to serve as active validation participants. This repurposes existing consumer hardware for network security rather than demanding specialized, energy-hungry ASICs or data centers.
- **Recycle:** Implementing cryptographic "purging" mechanisms to safely clear orphaned state data, recycling node storage space and ensuring long-term ecological balance within the ledger.

🏛 Governance: The PPOP Model

The Thuong Ho Protocol (THP) operates under a Public-Private-OpenSource Partnership (PPOP). This is not a static management structure but a living "Hydrological Ecosystem" where trust and efficiency flow in harmony.

1. Public: The Anchors

The Public sector provides the regulatory foundation and legitimacy for the network.

- Regulatory Oversight & Sandboxes: Establishing "Safe Waters" (Sovereign Sandboxes) in the Mekong Delta to pilot ESG tokenization and ODA disbursements.
- Legal Identity Bridge: Providing secure eKYC integration to ensure that every Farmer_ID represents a verified entity, giving international donors absolute peace of mind.

2. Private: The Lighthouses

Infrastructure giants and "Lighthouse Operators" provide the raw power required for a stateless future.

- Compute Power & Stability: Ensuring high-performance verification for mobile Skiff Nodes.
- SLA for Statelessness: Committing to a Service Level Agreement (SLA) that guarantees proof-generation speeds of under 2 seconds, maintaining the "fluidity" of the network.

3. OpenSource: The Distillers

A global community of developers and cryptographers who act as the ultimate filter for integrity.

- "Distilling" the Truth: Continuously auditing Poseidon hashes and Dilithium signatures to ensure the protocol remains "pure" and secure.
- Merit-Merge Governance: Protocol upgrades are driven by "Merit," not just capital. Contributors who optimize code to further reduce the 2KB proof size hold the most significant influence.

🌊 The Tidal Interaction

The PPOP model functions through a "Tidal Mechanism":

1. The Flow of Data: The Public sector defines the "rules of the river," the Private sector builds the "current" (infrastructure), and the OpenSource community ensures the "purity" of the water (data integrity).
2. Power Balance: If the Private sector becomes too centralized, the OpenSource community can propose algorithmic shifts to decentralize power. If conflicts arise within the community, the Public sector acts as an arbitrator based on established legal frameworks.

"PPOP is more than a governance model; it is a hydrological symphony. The Public keeps the river on course, the Private generates the power of the flow, and the OpenSource ensures the water remains untainted. This synergy makes Thuong Ho Protocol a decentralized yet protected entity—free, but profoundly responsible."

📄 Heritage and Licensing

We believe in "Distilling the Truth." The **Vietnamese Master Document** remains our primary heritage, while English serves as our bridge to the world.

To protect the "soul" and the "code" of the project, we utilize a **Dual License**:

- **MIT License** for the source code.
- **CC BY-SA 4.0** for the White Paper and architectural designs.

🔗 Join the Flow

The river of truth is moving. We invite cryptographers, developers, and visionaries to "merit-merge" with us.

- **GitHub Repository:** phthuongcc/thuong-ho-protocol
- **White Paper:** Available in the 📂00-earth-day-demo
  Note: The comprehensive White Paper is currently in its final distillation phase and will be officially released following the jury's feedback and community peer review.

🌍 Make Blockchain Green Again

Digital infrastructure shouldn't cost us the Earth. If you believe that the future of finance must be stateless, post-quantum, and energy-efficient, help us spread the word.

- **Reaction:** Give this post a ❤️ or 🦄 if you support green-tech innovation.
- **Fork & Experiment:** Try our Energy Efficiency Simulation and share your results!
- **Feedback:** We are distilling the full White Paper. Your feedback today will shape the heritage of tomorrow.

"Truth does not need to be protected; it only needs to be purged to shine." — **Sakura.**

🌍 Earth Day Special: Green Tech Implementation

We have included a dedicated **Earth Day Demo** folder in our repository, featuring:

1. **Energy Simulation:** A Python script proving the massive carbon footprint reduction of our $O(1)$ stateless architecture.
2. **Green ODA Schema:** Technical definition for climate-adaptation fund tracking.
3. **Smart Contract PoC:** A transparent fund disbursement model for the Mekong Delta.

"Leveraged Google Gemini as an AI collaborator to refine cryptographic architectures and optimize energy-efficiency simulations."

Dynamic ESG Reporting via Google Gemini API

To bridge the gap between raw cryptographic metrics and actionable climate context, we directly integrated the Google Gemini API (gemini-1.5-flash) into our Energy Efficiency Simulator.

Rather than relying on static estimates, our Python architecture dynamically calculates the CO2 footprint reduction achieved by our Verkle-based statelessness compared to legacy Merkle trees. Once the network simulation reaches enterprise scale (e.g., 1 billion transactions), the live data—including total CO2 saved and its equivalent in planted trees—is passed seamlessly to the Gemini API.

Gemini then acts as an automated Environmental Scientist, processing the mathematical baseline to generate dynamic, human-readable ESG insights. This integration proves that AI can transcend basic chatbot functionality to become a vital analytical engine for green digital infrastructure.

Demo 01: Energy Simulation [(energy_efficiency_sim.py)]

```
# Mô phỏng tiết kiệm năng lượng (Energy Simulation)
# So sánh lượng dữ liệu và điện năng tiêu thụ giữa Blockchain truyền thống
(Merkle) và Thương Hồ (Verkle) qua 1 triệu giao dịch.

import math

def simulate_energy_impact():
    print("="*65)
    print("THUONG HO PROTOCOL: GREEN TECH & EARTH IMPACT REPORT")
    print("Goal: Visualizing CO2 reduction in decentralized verification")
    print("="*65)

    # Giả định kỹ thuật:
    # 1 GB dữ liệu truyền tải tiêu thụ khoảng 0.06 kWh (số liệu ước tính
trung bình)
    # 1 kWh phát thải khoảng 0.4 kg CO2
    # Giả lập 1 triệu node xác thực toàn cầu
    KWH_PER_GB = 0.06
    CO2_PER_KWH = 0.4
    NETWORK_NODES = 1_000_000

    transactions = [10**3, 10**4, 10**6, 10**9] # Từ 1 nghìn đến 1 tỷ giao
dịch
```

```
